Comparison  
study

Conclusions

- Survey methodology to study the preferences of consumers
  - In a discrete choice experiment respondents must choose their preferred product in a series of choice sets contrasting multiple alternatives
  - Each alternative or profile in a set is characterized by a number of attributes
  - The attributes take on specific values or levels
- ⇒ The choices reveal the relative value that consumers attach to the different attributes of the product

HSW Safety Project

Game 3 of 10

Assume that you had to drive somewhere and that you could take two different routes. Below are details of the two ways that you could drive. Please take a look at the characteristics of the routes and select the route that you would be more likely to choose.

**Route A**

Speed	Travel time
90	10 minutes
80	8 minutes
100	8 minutes

**Route B**

Speed	Travel time
80	18 minutes
100	9 minutes
60	3 minutes

Time in free flow conditions	15 minutes
Time in slowed down conditions	11 minutes
Running costs	\$1.13
Toll costs	\$0.00
Deaths per year	4
Severe, permanent injuries per year	3
Injuries requiring hospitalisation per year	11
Minor injuries per year	24

Time in free flow conditions	20 minutes
Time in slowed down conditions	10 minutes
Running costs	\$1.98
Toll costs	\$5.00
Deaths per year	0
Severe, permanent injuries per year	5
Injuries requiring hospitalisation per year	9
Minor injuries per year	15

Which route would you choose?

If you could also choose not to travel

☐ Route A  
☐ I would stick with the same route

☐ Route B  
☐ I would choose not to travel

Introduction

Individualized  
design

$\mathcal{D}_B$   
 $KLP$   
 $MUI$   
 $ENT$

Comparison  
study

Conclusions

- Choice models are based on utility maximization
- The utility that individual  $n$  receives from alternative  $k$  in choice set  $s$

$$U_{ksn} = \mathbf{x}'_{ksn} \boldsymbol{\beta} + \varepsilon_{ksn}$$

- $\mathbf{x}_{ksn}$  the attribute levels of the alternative
  - $\boldsymbol{\beta}$  the relative importance of the attributes
- The conditional logit choice model
  - Probability that individual  $n$  chooses alternative  $k$  in choice set  $s$

$$p_{ksn}(\boldsymbol{\beta}) = \frac{e^{\mathbf{x}'_{ksn} \boldsymbol{\beta}}}{\sum_{t=1}^K e^{\mathbf{x}'_{tsn} \boldsymbol{\beta}}}$$

- Assumes a homogeneous population: all people equally value the product attributes

# Discrete choice analysis

 $KLP$   
 $MUI$   
 $ENT$

Comparison  
study

Conclusions

- The mixed logit choice model
  - Accounts for heterogeneity in the preferences
  - Individual-specific coefficients  $\beta_n$
  - Aggregate choice behavior in the population modeled with a heterogeneity distribution

$$\beta_n \sim \mathcal{N}(\mu, \Sigma)$$

- Unconditional mixed logit choice probability

$$p_{ksn} = \int \frac{e^{\mathbf{x}'_{ksn}\beta_n}}{\sum_{t=1}^K e^{\mathbf{x}'_{tsn}\beta_n}} \phi(\beta_n | \mu, \Sigma) d\beta_n$$

# Individualized design for the mixed logit choice model

Introduction

Individualized  
design

$\mathcal{D}_B$   
 $KLP$   
 $MUI$   
 $ENT$

Comparison  
study

Conclusions

- Bliemer and Rose (2010) constructed aggregate **locally**  $\mathcal{D}$ -efficient designs for the mixed logit choice model
- Generating aggregate Bayesian  $\mathcal{D}$ -efficient designs, taking the uncertainty about the model parameters into account, appeared infeasible in a reasonable amount of time

- Individualized design
  - $\beta_n$  assumed constant over all choice sets
  - The preferences of a specific individual are thus in essence modeled by a conditional logit choice model
  - Individual efficient designs with respect to the underlying conditional logit choice models

# Individualized design for the mixed logit choice model

Introduction

Individualized  
design

$\mathcal{D}_B$   
 $KLP$   
 $MUI$   
 $ENT$

Comparison  
study

Conclusions

- The choice experiments are sequentially generated for each person separately, based on choice information from the previously administered choice sets
- Tailored to the specific preferences of an individual
- Online, interactive choice experiments
  1. Assume a prior distribution  $f(\beta_n) \equiv \phi(\beta_n | \mu_0, \Sigma_0)$
  2. After respondent  $n$  has completed  $s - 1$  choice sets:  
Bayesian update of the prior information on  $\beta_n$

$$f(\beta_n | \mathbf{y}_n^{s-1}) = \frac{L(\beta_n | \mathbf{y}_n^{s-1}, \mathbf{X}_n^{s-1}) \phi(\beta_n | \mu_0, \Sigma_0)}{\int L(\beta_n | \mathbf{y}_n^{s-1}, \mathbf{X}_n^{s-1}) \phi(\beta_n | \mu_0, \Sigma_0) d\beta_n}$$

3. The next choice set is efficiently selected with the updated information
4. Repetition of steps 2 and 3 until a specific amount of choice sets is obtained

# Individualized design for the mixed logit choice model

Introduction

Individualized  
design

$\mathcal{D}_B$   
 $KLP$   
 $MUI$   
 $ENT$

Comparison  
study

Conclusions

- Comparison of four design criteria
  - Minimum posterior weighted  $\mathcal{D}$ -error ( $\mathcal{D}_B$ )
  - Novel criteria from optimal test design based on Kullback-Leibler divergence
    - Maximum expected Kullback-Leibler divergence between subsequent posteriors ( $KLP$ )
    - Maximum mutual information ( $MUI$ )
    - Minimum expected posterior entropy ( $ENT$ )

# Minimum posterior weighted $\mathcal{D}$ -error

- The (Bayesian) Fisher information matrix for design  $\mathbf{X}_n^S$  with  $S$  choice sets for individual  $n$

$$\mathbf{I}_{BFIM}(\beta_n, \mathbf{X}_n^S) = -\mathbb{E} \left[ \frac{\partial^2 \log[L(\beta_n | \mathbf{y}_n^S, \mathbf{X}_n^S) f(\beta_n)]}{\partial \beta_n \partial \beta_n'} \right]$$

with  $f(\beta_n)$  a prior for  $\beta_n$

- Assuming a normal prior with covariance matrix  $\Sigma_0$

$$\begin{aligned} \mathbf{I}_{BFIM}(\beta_n, \mathbf{X}_n^S) &= \mathbf{I}_{FIM}(\beta_n, \mathbf{X}_n^S) + \Sigma_0^{-1} \\ &= \sum_{s=1}^S \mathbf{X}_{sn}' (\mathbf{P}_{sn} - \mathbf{p}_{sn} \mathbf{p}_{sn}') \mathbf{X}_{sn} + \Sigma_0^{-1} \end{aligned}$$

Introduction

Introduction

Individualized  
design

$\mathcal{D}_B$   
 $KLP$   
 $MUI$   
 $ENT$

Comparison  
study

Conclusions

- Bayesian  $\mathcal{D}$ -efficient designs: minimize  $\mathcal{D}$ -error averaged over a weighting distribution for  $\beta_n$
- To select the  $s$ th choice set, minimize

$$\int \det[\mathbf{I}_{BFIM}(\beta_n, \mathbf{X}_n^s)]^{-1/p} f(\beta_n | \mathbf{y}_n^{s-1}) d\beta_n$$

# Maximum expected Kullback-Leibler divergence between subsequent posteriors

Introduction

Individualized  
design

$\mathcal{D}_B$   
 $KLP$   
 $MUI$   
 $ENT$

Comparison  
study

Conclusions

- Kullback-Leibler divergence between two densities  $f$  and  $g$  for a continuous variable  $X$

$$KL(f, g) = \int f(x) \log \frac{f(x)}{g(x)} dx$$

- For any  $f$  and  $g$ ,  $KL$  is non-negative and zero in case of equal densities
- $KL(f, g)$  increases as the two densities become more divergent
- “Distance between two densities”
- Not a real distance measure (for instance non-symmetric:  $KL(f, g) \neq KL(g, f)$ )

# Maximum expected Kullback-Leibler divergence between subsequent posteriors

Introduction

Individualized  
design

$\mathcal{D}_B$   
 $KLP$   
 $MUI$   
 $ENT$

Comparison  
study

Conclusions

- To select the  $s$ th set in a choice experiment, maximize the expected Kullback-Leibler distance between the current posterior distribution of  $\beta_n$  and the updated posterior one obtains with the answer to the  $s$ th choice set

$$\sum_{k=1}^K \pi(y_{ksn} | \mathbf{y}_n^{s-1}) KL[f(\beta_n | \mathbf{y}_n^{s-1}), f(\beta_n | \mathbf{y}_n^{s-1}, y_{ksn})]$$

with

$$\pi(y_{ksn} | \mathbf{y}_n^{s-1}) = \int p_{ksn}(\beta_n) f(\beta_n | \mathbf{y}_n^{s-1}) d\beta_n$$

# Maximum mutual information

- Mutual information between two variables  $X$  and  $Y$

$$I_M(X, Y) = \int_Y \int_X f(x, y) \log \frac{f(x, y)}{f(x)f(y)} dx dy$$

- Kullback-Leibler distance between the joint distribution of  $X$  and  $Y$  and their distribution in case of independence
  - Expresses how much information one variable holds with respect to the other
- To select the  $s$ th set in a choice experiment, maximize the mutual information between the individual coefficients  $\beta_n$  and the choice for the next set, given the choice data of the previously administered sets

$$\sum_{k=1}^K \int f(\beta_n, y_{ksn} | \mathbf{y}_n^{s-1}) \log \frac{f(\beta_n, y_{ksn} | \mathbf{y}_n^{s-1})}{f(\beta_n | \mathbf{y}_n^{s-1}) \pi(y_{ksn} | \mathbf{y}_n^{s-1})} d\beta_n$$

# Minimum expected posterior entropy

Introduction

Individualized  
design

$\mathcal{D}_B$   
 $KLP$   
 $MUI$   
 $ENT$

Comparison  
study

Conclusions

- Entropy for a continuous variable  $X$  and density  $f(x)$

$$H(X) = - \int f(x) \log f(x) dx$$

- Measure of uncertainty
- To select the  $s$ th set in a choice experiment, minimize the expected posterior entropy, or equivalently maximize

$$\sum_{k=1}^K \pi(y_{ksn} | \mathbf{y}_n^{s-1}) \int f(\beta_n | \mathbf{y}_n^{s-1}, y_{ksn}) \log f(\beta_n | \mathbf{y}_n^{s-1}, y_{ksn}) d\beta_n$$

# Connections among the Kullback-Leibler design criteria

- *KLP* is the expected Kullback-Leibler distance between the current and the updated posterior

$$\sum_{k=1}^K \pi(y_{ksn} | \mathbf{y}_n^{s-1}) KL[f(\boldsymbol{\beta}_n | \mathbf{y}_n^{s-1}), f(\boldsymbol{\beta}_n | \mathbf{y}_n^{s-1}, y_{ksn})]$$

- *MUI* is the expected Kullback-Leibler distance between the updated and the current posterior

$$\sum_{k=1}^K \pi(y_{ksn} | \mathbf{y}_n^{s-1}) KL[f(\boldsymbol{\beta}_n | \mathbf{y}_n^{s-1}, y_{ksn}), f(\boldsymbol{\beta}_n | \mathbf{y}_n^{s-1})]$$

- *ENT* is the expected Kullback-Leibler distance between the updated posterior and a uniform distribution

# Comparison study

Introduction

Individualized  
design

$\mathcal{D}_B$   
 $KLP$   
 $MUI$   
 $ENT$

Comparison  
study

Conclusions

- Multiple experimental setups

Scenario 1	$3^3/2/15$
Scenario 2	$2 \times 3 \times 2 \times 3/3/15$
Scenario 3	$3 \times 2^4/2/15$
Scenario 4	$3 \times 2 \times 3/3/15$

- 50 respondents
- Response simulation repeated 100 times

# Estimation accuracy

Mean  $RMSE_{\mu}$ ,  $RMSE_{\Sigma}$  and  $RMSE_{\beta}$  values obtained with  $KLP$ ,  $MUI$ ,  $ENT$  and  $\mathcal{D}_B$  for the different scenarios

⇒ No significant differences in estimation accuracy for scenario 1, 2 and 4

⇒ In scenario 3,  $KLP$  outperforms the other methods

## Computation time

Average computation time (seconds) to select an additional choice set with  $KLP$ ,  $MUI$ ,  $ENT$  and  $\mathcal{D}_B$  using various numbers of draws

	Scenario 1			Scenario 2		
	512	1024	2048	512	1024	2048
$KLP$	0.074	0.152	0.285	1.726	3.381	6.729
$MUI$	0.082	0.152	0.293	1.773	3.484	6.924
$ENT$	0.090	0.168	0.328	1.972	3.866	7.674
$\mathcal{D}_B$	1.789	3.269	6.523	35.689	71.277	142.296

# Computation time

Introduction

Individualized  
design

$\mathcal{D}_B$   
 $KLP$   
 $MUI$   
 $ENT$

Comparison  
study

Conclusions

	Scenario 3			Scenario 4		
	512	1024	2048	512	1024	2048
$KLP$	0.207	0.402	0.805	0.219	0.418	0.809
$MUI$	0.215	0.414	0.816	0.223	0.426	0.836
$ENT$	0.242	0.468	0.914	0.246	0.473	0.934
$\mathcal{D}_B$	5.207	10.375	20.671	3.855	7.702	15.436

- ⇒ Impressive decrease in computation time from using the Kullback-Leibler design criteria instead of  $\mathcal{D}_B$
- ⇒ The  $\mathcal{D}_B$  computation times are approximately 20 times the  $KLP$  times

# Conclusions

Introduction

Individualized  
design

$\mathcal{D}_B$   
 $KLP$   
 $MUI$   
 $ENT$

Comparison  
study

Conclusions

- This research focusses on improving the practicability of individualized choice design for the mixed logit choice model using criteria from optimal test design
- Comparison of four design algorithms
  - The efficiency to estimate the mixed logit choice model of the designs obtained with the four criteria is equivalent
  - The Kullback-Leibler criteria are preferred over  $\mathcal{D}$ -efficiency due to their low complexity, yielding a huge decrease in computation time
  - The Kullback-Leibler criteria warrant the feasibility of individualized choice design
